

ARGoS-Blockchain interface

WORK IN PROGRESS

September 12, 2020

Abstract

This technical report documents the installation and use of the ARGoS-Blockchain interface. This interface allows for conducting experiments in the robot swarm simulator ARGoS and the smart contract blockchain framework Ethereum. The blockchain part uses the container software Docker in order to facilitate the installation and the parallelization of the blockchain nodes. The use of blockchain-based smart contracts provides a framework for managing security issues in robot swarms. The interface is a convenient way to prototype blockchain-based control software in robot swarms. Byzantine robots, that is, robots that behave in an unintended way can disrupt the swarm behavior. In this technical report, we detail the motivation, setup, and usage of the ARGoS-blockchain interface.

1 Introduction

Several recent works have addressed the combination of blockchain technology and swarm robotics Strobel et al. (2018a); Strobel and Dorigo (2018); Strobel et al. (2018b); Castelló Ferrer (2016); Pacheco et al. (2020a,b). This combination proves useful for security, consensus finding, robot economies, robot-as-a-service, and potentially many other applications in robot swarms. Being a young research field, it misses standardized research platforms. However, conducting experiments involving robot swarms and blockchain technology requires a suitable testbed. A widely used framework consists of the Pi-puck robot platform running the Ethereum blockchain network. However, not every researcher has access to physical robots, obtaining and maintaining them be both time-intensive and cost-intensive, not to mention the lengthy execution of experiments. Therefore, a simulation testbed is needed to quickly try and test different controllers and scenarios. The ARGoS robot swarm simulator (Pinciroli et al., 2012) is the state-of-the-art research platform to conduct simulations in swarm robotics. Such a framework proves useful both for researchers who do not have access to a suitable robot platform, such as the Pi-puck robot. Additionally, a suitable platform is important before running time-consuming experiments with real robots.

In general, in swarm robotics research, each robot is a blockchain node, and contributes to the maintenance of the system by exchanges blockchain infor-

Figure 2: For each robot, the ARGoS-Blockchain interface establishes a connection to the Ethereum blockchain via a Docker container and shell scripts that provide templates for executing Ethereum (geth) functions.

mation. To link ARGoS and blockchain software, we developed the ARGoS-Blockchain interface that provides access to the blockchain nodes for the robots (Figure 3). The interface is intended to facilitate research in blockchain-based robot swarms by allowing to call blockchain functions in ARGoS. Additionally, using Docker makes it easy to install and run the interface on different platforms.

2 Software availability

The open-source software is available at GitHub: the blockchain module is available at ¹ and the ARGoS module is available at ².

3 Overview

The implementation of the custom Ethereum network is based on Capgemini AIE’s Ethereum Docker³. Docker containers (Merkel, 2014) contain all the necessary dependencies to run specific applications and are more lightweight than a virtual machine. In our setup, for each robot, the Ethereum implementation *geth* is executed in a separate Docker container. The simulated robots maintain a *custom* Ethereum network, i.e., a network that is shared among the simulated robots and independent of Ethereum’s main network. Different containers can communicate with each other via channels.

In order to execute an Ethereum function (e.g., create a new smart contract) from ARGoS, a robot uses its C++ controller to attach to the Docker container. The Docker containers provide shell scripts⁴ with customizable templates (e.g., one of the templates compiles the smart contract, uses the binary code to send a blockchain transactions, and waits until the contract is mined). Via Ethereum’s IPC (interprocess communications) interface, the shell scripts execute the Ethereum functions.

We use an auxiliary ‘bootstrap’ node for publishing the smart contract to the blockchain at the beginning of each run of the simulations (Figure ??). The bootstrap node then mines the smart contract and sends the contract address and the ABI (application binary interface; the ABI specifies which functions a smart contract provides and how to call them) to the controllers of the robots. As soon as this is done, the bootstrap node is removed from the network. The bootstrap node is not necessarily required and the smart contract could also be created by a robot. However, we used an auxiliary node to make sure (i) that the smart contract is available at the start of the actual experimental run and (ii) that robots have the same initial conditions in all experiments.

The experiments were conducted on a computer cluster. To simulate the limited hardware of real robots, one core with 2.0 GHz and 1.8 GB of memory was assigned to each Docker container⁵. The communication channels between the Docker containers were only established when robots were within a 50 cm communication range in order to simulate the local communication capabilities of real robots.

The description in this report is intended to allow everyone to run blockchain-based robot experiments in simulation. There is no need for specific hardware but powerful CPU and RAM are advantageous for fluent experiments.

The ARGoS-Blockchain interface is composed of two modules.

3.0.1 Module 1: Blockchain part

Module 1 allows for creating an Ethereum network with several nodes, where each node is located in a separate Docker container. For the ARGoS-Blockchain interface, the interaction with the Ethereum nodes is done via C++, using the code in the following repository:

<https://github.com/Pold87/robot-swarms-need-blockchain>

This repository contains one module of the ARGoS-Blockchain interface that is described in the article “Blockchain Technology Secures Robot Swarms: A Comparison of Consensus Protocols and Their Resilience to Byzantine Robots by Strobel, V., Castello Ferrer, E., and Dorigo, M.”

⁴The interface uses shell scripts, since, during development, it became evident that they are executed much faster than other Ethereum APIs.

⁵This is a reasonable choice as a robot’s computer could easily have such characteristics. It is also a convenient choice because on a computer with 2.0 GHz and 1.8 GB of RAM, Ethereum works “out-of-the-box,” without any modifications; therefore, any interested user can obtain the most recent release of Ethereum from the official depository and use it with our publicly available ARGoS-Blockchain interface.

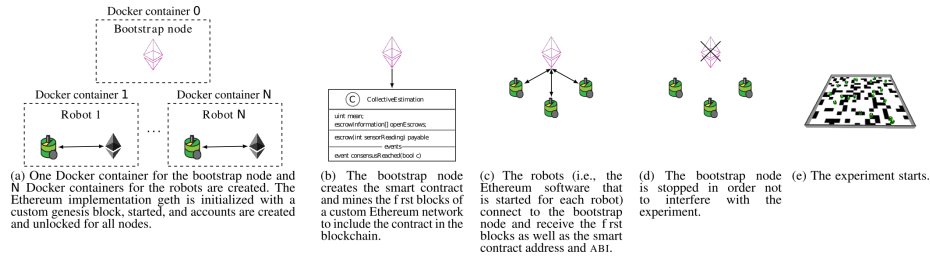

Figure 3: This scheme gives an overview of the workflow of the ARGoS-Blockchain interface

For debugging purposes or for creating your own private Ethereum network, you can also use this module without ARGoS.

3.0.2 Module 2: ARGoS part

4 Setup

The following setup steps describe the installation of the ARGoS-Blockchain interface using Linux as operating system. There is a video tutorial at https://www.youtube.com/watch?v=IqiTJK_uzUY that described the entire installation process, starting from a blank Ubuntu 20.04 LTS installation.

4.1 Requirements

- Sufficient disk space (at least 16 GB)
- Docker
- ARGoS⁶ and the ARGoS e-puck robot plugin⁷ (see installation instructions below)

4.2 Installation of Docker

The installation of the Docker Engine on Ubuntu is described at <https://docs.docker.com/engine/install/ubuntu/>. Below, you will find information about how to control the Docker Engine as a non-root user.

1. By default, the execution of Docker commands requires root user privileges. To facilitate the execution of Docker commands, it is possible to run Docker as non-root user (i.e., without `sudo`) as follows (see <https://docs.docker.com/engine/install/linux-postinstall/> for more detailed instructions).

⁶<https://github.com/ilpincy/argos3>

⁷<https://github.com/demiurge-project/argos3-epuck>

```
$ sudo groupadd docker
$ sudo usermod -aG docker $USER
$ newgrp docker
```

2. Additionally, restarting the Docker engine via `systemctl` requires sudo privileges. To control Docker as a normal user, add an entry in the sudoers file (replace `volker` with your user name).

```
$ sudo visudo -f /etc/sudoers.d/docker

volker ALL= NOPASSWD: /bin/systemctl restart docker.service
volker ALL= NOPASSWD: /bin/systemctl start docker.service
volker ALL= NOPASSWD: /bin/systemctl stop docker.service
```

4.3 Installation of ARGoS and the ARGoS e-puck plugin

This section briefly describes the setup of ARGoS and the ARGoS e-puck plugin. Please carefully read the README files of the respective repositories for more information.

1. Obtain the source code of both repositories

```
$ git clone https://github.com/ilpincy/argos3.git
$ git clone https://github.com/demiurge-project/argos3-epuck.git
```

2. Install the dependencies.

```
$ sudo apt-get install cmake g++ libfreeimage-dev libfreeimageplus-dev \
qt5-default freeglut3-dev libxi-dev libxmu-dev liblua5.3-dev \
lua5.3 doxygen graphviz graphviz-dev asciidoc
```

2. Build and install ARGoS system-wide.

```
$ cd argos3/
$ mkdir build
$ cd build
$ cmake ../src
$ make
$ make doc
$ sudo make install
$ sudo ldconfig
```

3. Verify that the installation was succesful.

```
$ argos3 --version
ARGOS_VERSION=3.0.0-beta56
ARGOS_INSTALL_PREFIX=/usr/local
ARGOS_USE_DOUBLE=ON
ARGOS_WITH_LUA=ON
ARGOS_BUILD_FLAGS= -Wall -g -ggdb3
```

4. Build and install the ARGoS-epuck plugin.

```
$ cd ../../argos3-epuck/  
$ mkdir build  
$ cd build  
$ cmake ../src  
$ make  
$ sudo make install  
$ sudo ldconfig
```

4.4 Obtain Source Code

1. Create a base folder for storing the two modules of the ARGoS-Blockchain interface.

```
$ mkdir AB-interface/  
$ cd AB-interface/  
$ pwd  
/home/volker/software/AB-interface
```

2. Obtain the source code for the blockchain module.

```
$ git clone https://github.com/Pold87/AB-interface-Blockchain-module.git \  
Blockchain-module
```

3. Obtain the source code for the ARGoS module.

```
$ git clone https://github.com/Pold87/AB-interface-ARGoS-module.git ARGoS-module
```

4.5 Installation — Module 1: Blockchain module

1. Obtain the Ethereum source code and store it in the folder `custom-geth/`. Please note that Ethereum is compiled locally here. While there are Docker images for Ethereum, this allows for more customization (e.g., if you want to change the size of the DAG file, as explained in Section 6.1).

```
$ cd Blockchain-module/ && cd geth/  
$ git clone https://github.com/ethereum/go-ethereum.git custom-geth/
```

2. Create the Ethereum image and initialize the Docker swarm.

```
$ docker build -t mygeth .  
$ docker swarm init
```

3. Next, we need to link the blockchain module and the ARGoS module. First, set the ARGoS folder in the file `global_config_blockchain.sh`.

```
$ nano ../local_scripts/global_config_blockchain.sh
ARGOSFOLDER="/home/volker/software/AB-interface/ARGoS-module"
```

4. Then, set the variable `DOCKERBASE` in the file `global_config.sh` of the ARGoS module (Module 2) to the full path where the blockchain module (Module 1) repository is located on your computer, for example:

```
$ nano /home/volker/software/AB-interface/ARGoS-module/global_config.sh
DOCKERBASE='/home/volker/software/AB-interface/Blockchain-module/'
```

5. In order to be able to mine, you need to create the DAG datasets. Creating the files requires approximately 2 GB disk space and the execution of the script can take several minutes. If you want to run the software on limited hardware, you can decrease the size of the DAG dataset by carrying out the modifications described in Section 6.1.

```
cd local_scripts/
bash create_dag.sh
```

4.6 Installation — Module 2: ARGoS module

1. Compile the ARGoS code.

```
$ cd /home/volker/software/AB-interface/ARGoS-module/
$ mkdir build/
$ cd build/
$ cmake ..
$ make
```

5 Run

Usually, the network is created when a swarm robotics experiment is started, using one of the starter scripts in the folder `ARGoS-module/starters/`. Start with a plain experiment to see if the installation was successful. The command needs to be executed from the base folder of the ARGoS part of the blockchain interface.

```
$ bash starters/1_Plain.sh
```

You can also start the Ethereum network without ARGoS, using the following command:

```
$ bash local_scripts/start_network.sh <number of nodes>
```

That is, `bash local_scripts/start_network.sh 5`, would create a private Ethereum network with 5 nodes.

6 Modifications

6.1 Changes for limited hardware

The target platform of the ARGoS-blockchain interface are robots with limited hardware. The mining algorithm Proof-of-Work requires a 1 GB dataset by default that must be stored in the memory. On a Pi-puck, Proof-of-Work does not run out-of-the-box due the large DAG file that has to be kept in memory. In order to reduce the DAG file size (warning: this will likely decrease the security of the network in a real-world deployment but is fine in a private testnet), modify the file `go-ethereum/consensus/ethash/algorithm.go` as described below.

1. Change

```
datasetInitBytes = 1 << 30 // Bytes in dataset at genesis
```

to

```
datasetInitBytes = 1 << 20 // Bytes in dataset at genesis
```

2. Comment out the following lines:

```
//if epoch < maxEpoch {  
    //return cacheSizes[epoch]  
    //}
```

and

```
//if epoch < maxEpoch {  
    //return datasetSizes[epoch]  
    //}
```

7 Debugging

First, check that the Docker container for the bootstrap node and the individual containers for the robots are running:

```
$ docker service ps ethereum_bootstrap --no-trunc  
$ docker service ps ethereum_eth --no-trunc
```

If the value of DESIRED STATE is RUNNING, take a look at the log files of the containers.

```
$ docker logs ethereum_bootstrap.1.ik6isqahrmsgzkzkj4pbb2zd5
```

8 Usage

The functions of the interface can be found in the file `/interface/generic_interface.cpp`.

- `unlockAccount`: Unlock the coinbase account.

- `startMining`: Start the mining process using one thread.
- `stopMining`: Stop the mining process.
- `addPeer`: Add a peer based on its enode.
- `removePeer`: Add a peer based on its enode.
- `scInterface`: A generic smart contract interface.
- `scReturn0(string function, long long wei)`:

8.1 Compilation

After changes to the ARGoS files are made, the code needs to be recompiled.

```
$ cd build/
$ make
```

Acknowledgements

Volker Strobel and Marco Dorigo acknowledge support from the Belgian F.R.S.-FNRS, of which they are a Research Fellow and a Research Director respectively. Alexandre Pacheco acknowledges support from the Faculty of Applied Sciences of the Université Libre de Bruxelles.
